## Homework 2

1) Finding Peaks in a $n \times n$ matrix ( 10 pts ).

However, there is a more efficient peak finding algorithm. The algorithms is as follows:

1. Look at the middle row and column, and the boundaries
2. Find the maximum within these rows/columns
3. If it is a peak (larger than all 4 neighbors):

- return element

4. Else:

- Look at larger neighbor
- Go to step 1 with the quadrant.

| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 9 | 3 | 5 | 2 | 4 | 9 | 8 | 0 |
| 0 | 7 | 2 | 5 | 1 | 4 | 0 | 3 | 0 |
| 0 | 9 | 8 | 9 | 3 | 2 | 4 | 8 | 0 |
| 0 | 7 | 6 | 3 | 1 | 3 | 2 | 3 | 0 |
| 0 | 9 | 0 | 6 | 0 | 4 | 6 | 4 | 0 |
| 0 | 8 | 9 | 8 | 0 | 5 | 3 | 0 | 0 |
| 0 | 2 | 1 | 2 | 1 | 1 | 1 | 1 | 0 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

1. Correctness:
-If you enter a quadrant, this means that the maximum element on the border of the quadrant is not a peak. -When the algorithm stops inside a quadrant, the peak is internal to the quadrant so it is a peak in the array
2. Complexity:
3. Given $n x n$ matrix, you will look into middle row( $n$ ), middle column(n) and borders $(c * n)$ $=n+n+c n$.
4. Then call function recursively in $\frac{n}{2} x \frac{n}{2}$ matrix. $=$ middle row $\left(\frac{n}{2}\right)$, middle column $\left(\frac{n}{2}\right)$ and new borders $\left(c * \frac{n}{2}\right)$.
5. Total complexity of function is:

- $\quad F(n)=F\left(\frac{n}{2}\right)+c n$.
- $F\left(\frac{n}{2}\right)=F\left(\frac{n}{4}\right)+c \frac{n}{2}$. Similarly $F\left(\frac{n}{4}\right)=F\left(\frac{n}{8}\right)+c \frac{n}{4} \ldots$
- Writting in terms of $F(n): F(n)=F(1)+c\left(2+4+. .+\frac{n}{4}+\frac{n}{2}+n\right)$
- Largest term is $n$, so function is $\boldsymbol{O}(\boldsymbol{n})$

## Greedy Ascend Algorithm (10 pts).

Describe the greedy ascend algorithm and come up with a $5 \times 5$ matrix where greedy ascend will stop at the 23erd element.

| 19 | 20 | 21 | 22 | 23 |
| :---: | :---: | :---: | :---: | :---: |
| 18 | 17 | 16 | 15 | 14 |
| 3 | 2 | 1 | 12 | 13 |
| 4 | 0 | 0 | 11 | 10 |
| 5 | 6 | 7 | 8 | 9 |

## 2) Stacks and Queues ( $\mathbf{1 0} \mathbf{p t s}$ ):

One common interview question is to show how to create a stack from other abstract data types(ADT). Your task is to write pseudocode to implement a stack using two queues with the following primitives of queues: EMPTY(Q), ENQUEUE (Q, element), DEQUEUE(Q). Your stack should have the following primitives: PUSH (S, element) and $\operatorname{POP}(S)$. What is the time complexity for each of the operations PUSH (s, element) and $\operatorname{POP}(\mathrm{s})$ ?
Push(s, e)
ENQUEUE(Q1 ,e)
Pop(s)
if EMPTY(Q1) (ALWAYS CHECK)
return error
while not EMPTY(Q1)
temp = pop(Q1);
if EMPTY(Q1) (temp = last element)
ENQUEUE all elements from Q2 to Q1
return temp
else
ENQUEUE(Q2, temp)
Complexity: Push = O(1), POP = O(n)

Solution 2 (POP efficient):

Push(s,e)
ENQUEUE(Q2,e)
ENQUEUE all elements from Q1 to Q2
ENQUEUE all elements from Q2 to Q1

## Pop(s)

if EMPTY(Q1) (ALWAYS CHECK)
return error
else
return DEQUEUE(Q1)

Complexity: Push = O(n), POP = O(1)

## 3) Analysis of algorithms ( $\mathbf{1 0} \mathbf{~ p t s ) : ~}$

| INSERTION_SORT $(A[1 . n])$ | Cost | Times |  |
| :--- | :---: | :---: | :---: |
| 1. | for $j \leftarrow 2$ to $n$ | $C_{1}$ | $n$ |
| 2. | key $\leftarrow A[j]$ | $C_{2}$ | $n-1$ |
| 3. | $i \leftarrow j-1$ | $C_{3}$ | $n-1$ |
| 4. | while $i>0$ and $A[i]>$ key | $C_{4}$ | $\sum_{j=2}^{n} t_{j}$ |
| 5. | $A[i+1] \leftarrow A[i]$ | $C_{5}$ | $\sum_{j=2}^{n}\left(t_{j}-1\right)$ |
| 6. | $i \leftarrow i-1$ | $C_{6}$ | $\sum_{j=2}^{n}\left(t_{j}-1\right)$ |
| 7. | $A[i+1] \leftarrow$ key | $C_{7}$ | $n-1$ |

(a) Let $t_{j}$ denote the number of times the while loop test in line 4 is executed for that value of $j$. Fill in for each line of instruction, the number of times the instruction is executed.
(b) Derive the expression for the running time of INSERTION_SORT in terms of $n, C_{i}$, and $t_{j}$. Let $T(n)=$ running time of INSERTION_SORT.

$$
T(n)=C_{1} n+C_{2}(n-1)+C_{3}(n-1)+C_{4} \sum_{j=2}^{n} t_{j}+C_{5} \sum_{j=2}^{n}\left(t_{j}-1\right)+C_{6} \sum_{j=2}^{n}\left(t_{j}-1\right)+C_{7}(n-1)
$$

(c) What is $t_{j}$ for the best-case scenario, i.e., when the running time of the algorithm is the smallest. Use that to derive the expression for the best-case running time of INSERTION_SORT in terms of $n$ and $C_{i}$. What is the best-case time complexity of INSERTION_SORT using the big-O notation?

The array is already sorted. All $t_{j}$ are 1 . Therefore,

$$
\begin{aligned}
T(n) & =C_{1} n+C_{2}(n-1)+C_{3}(n-1)+C_{4}(n-1)+C_{7}(n-1) \\
& =\left(C_{1}+C_{2}+C_{3}+C_{4}+C_{7}\right) n-\left(C_{2}+C_{3}+C_{4}+C_{7}\right)
\end{aligned}
$$

$T(n)=O(n)$. (In fact, $T(n)=\Theta(n)$.)
(d) What is $t_{j}$ for the worst-case scenario, i.e., when the running time of the algorithm is the largest. Use that to derive the expression for the worst-case running time of INSERTION_SORT in terms of $n$ and $C_{i}$. What is the worst-case time complexity of INSERTION_SORT using the big-O notation?

The array is in reverse sorted order. We have to compare the $j$-th element with the previous $(j-1)$ elements. We also need an additional test to get out of the while-loop. Therefore, $t_{j}=j$. Hence,

$$
\begin{aligned}
T(n) & =C_{1} n+C_{2}(n-1)+C_{3}(n-1)+C_{4} \sum_{j=2}^{n} j+C_{5} \sum_{j=2}^{n}(j-1)+C_{6} \sum_{j=2}^{n}(j-1)+C_{7}(n-1) \\
& =C_{1} n+C_{2}(n-1)+C_{3}(n-1)+C_{4}\left(\frac{n(n+1)}{2}-1\right)+C_{5} \frac{n(n-1)}{2}+C_{6} \frac{n(n-1)}{2}+C_{7}(n-1) \\
& =\left(\frac{C_{4}+C_{5}+C_{6}}{2}\right) n^{2}+\left(C_{1}+C_{2}+C_{3}+\frac{C_{4}-C_{5}-C_{6}}{2}+C_{7}\right) n-\left(C_{2}+C_{3}+C_{4}+C_{7}\right) .
\end{aligned}
$$

$$
T(n)=O\left(n^{2}\right) .\left(\operatorname{In} \text { fact, } T(n)=\varrho\left(n^{2}\right) \cdot\right)
$$

## 4) Recursive Algorithms ( $\mathbf{1 0} \mathbf{~ p t s}$ ):

The following $\mathrm{C}++$ function permute () prints all permutations of the given string. For example, a call of permute ( 0,2 ) on "ABC" should print the following (order does not matter).

## ABC ACB BAC BCA CBA CAB

Complete the following code and briefly explain what happens to the string in every recursive call. (Note: you shouldn't need to write more than 5 lines of code).

```
#include <iostream>
using namespace std;
char str[] = "ABC";
void swap (char *x, char *y) {
    char temp;
    temp = *x;
    *x = *Y;
    *Y = temp;
}
void permute(int i, int n) {
    int j;
    if (i==n) {
        cout << str << " ";
    }else{
        for(j=i;j<=n;j++)
        {
            //your code goes here
            swap((str + i), (str+j));
            permute(i+1, n);
            swap((str+i),(str+j));
        }
    }
}
```
