**Function:**
- a connection between sets in which each element of the first set corresponds with exactly one element of the second set
  - the reverse is not necessarily true, but if it is, the function is one-to-one (more about these functions in Lesson 27)
- the first set is called the domain and the second set is called the range
  - an example of a function is the set of students in this classroom and their birthdays
    - each student has exactly one day when they were born, but that day could correspond with more than one student (function)
      - the set of students are the domain and the set of birthdays are the range
  - another example of a function is the set of students at Purdue and their student ids
    - each student has exactly one student id and each student id corresponds with exactly one student (one-to-one function)
      - the set of students are the domain and the set of student ids are the range

**Functions as equations:**
- in terms of an equation, a function can be thought of as a rule that states what operations are performed on the inputs (the values that are plugged into a function)
  - for the function \( f(x) = \frac{1-x^2}{3} \), we need to square each input, then negate the value, then add 1, and finally divide by 3
- the domain is the set of inputs and the range is the set of outputs
  - if I replace \( x \) with 0, then 0 is my input and it is an element of the domain; plugging 0 in for \( x \) results in \( f(0) = \frac{1-0^2}{3} = \frac{1}{3} \), which simplifies to \( f(0) = \frac{1}{3} \); so \( \frac{1}{3} \) is an element of the range
- in order for an equation to be a function, every input can have only one output
- functions are represented by arbitrary letters, such as \( f, g, h \) ...
**Domain:**
- the set of inputs for which a function is defined, which means a meaningful output is produced
  - if an input makes a function undefined, that input is not part of the domain

For many types of functions, the domain is unrestricted. This means that any real number can be plugged into the function, and a meaningful output will be produced. Linear functions (which we’ll cover in Lesson 20) are one example, and quadratic functions (which we’ll cover in Lessons 23 & 24) are another.

<table>
<thead>
<tr>
<th>Linear Function</th>
<th>Quadratic Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>$f(x) = ax + b$</td>
<td>$f(x) = ax^2 + bx + c$</td>
</tr>
<tr>
<td>Domain: $(-\infty, \infty)$</td>
<td>Domain: $(-\infty, \infty)$</td>
</tr>
</tbody>
</table>

For each of these functions, the domain is all real numbers $(-\infty, \infty)$. This means we could plug in any real number from negative infinity to positive infinity, and we will get a real number back as our output.

The reason this is the case is because there is nothing to restrict the domain of either of these functions. There are no fractions, so we don’t have to worry about restricting a value that will result in a denominator of zero. And there are no square roots (or any other even roots), so we don’t have to worry about restricting values that will result in a negative radicand. These are two types of restrictions we’ll focus on going forward; later we’ll also see how logarithms can restrict the domain of a function.
As mentioned on the previous page, there are two ways (for now) that the domain of a function can be restricted. We could have a rational function, which just means a function defined by a fraction, or we could have a function defined by a square root.

- **rational functions (fractions)**
  - **denominator cannot equal zero**
  - if $f(x) = \frac{1}{x}$, then $x \neq 0$ and the domain is all real numbers except 0

For a function such as $f(x) = \frac{1}{x}$, $x$ cannot be 0 because we can never divide by 0 ($x \neq 0$). That means $x$ can less than 0 ($x < 0$) or $x$ can be greater than 0 ($x > 0$), but it cannot equal 0. This is expressed using interval notation as $(-\infty, 0) \cup (0, \infty)$; the interval $(-\infty, 0)$ represents the set of negative numbers ($x < 0$) and the interval $(0, \infty)$ represents the set of positive numbers ($x > 0$). Notice that in both intervals, $(-\infty, 0)$ and $(0, \infty)$, there is a parenthesis on 0. That means that 0 is not part of either interval. For the function $f(x) = \frac{1}{x}$ we can choose inputs that are as close to zero as we’d like, but cannot use 0 as an input because it will produce a real number as an output (meaning it makes the function undefined).
- **square root functions**
  - cannot take the even root of a negative value
  - if \( g(x) = \sqrt{x} \), then \( x \geq 0 \) and the domain is all real numbers greater than or equal to 0

For a function such as \( g(x) = \sqrt{x} \), \( x \) cannot be negative because it is impossible to take the even root of a negative number and get a real number in return (\( x \geq 0 \)). That means \( x \) can equal 0, or be larger than 0; this is expressed using interval notation as \([0, \infty)\). The square bracket on 0 indicates that 0 is part of the interval, so 0 and any number bigger than 0 can be used as an input for the function \( g(x) = \sqrt{x} \) and they will all produce meaningful outputs (they will not make the function undefined).

**Example 1:** Find the domain of each of the following functions, and list in interval notation. **Use a number line to convert from inequalities to intervals, if necessary.**

a. \( f(x) = \sqrt{2x + 7} \)

b. \( g(x) = \sqrt{8 - 3x} \)
c. \( h(x) = 2 + \sqrt{3 + x} \)  

d. \( j(x) = 1 - \sqrt{1 - 2x} \) 

\[
1 - 2x \geq 0 \\
1 \geq 2x \\
\frac{1}{2} \geq x \\
x \leq \frac{1}{2} \\
\frac{1}{2} \geq x \quad \text{and} \quad x \leq \frac{1}{2} \quad \text{are both saying the same thing, I just prefer} \\
x \leq \frac{1}{2} \quad \text{because I like to have} \ x \quad \text{on the left hand side of my inequalities. But} \\
\text{again, the inequalities mean the same thing regardless.}
\]

\( \left(-\infty, \frac{1}{2}\right] \) 

e. \( k(x) = 5 + \sqrt{\frac{4-x}{3}} \)  

f. \( l(x) = 3 - \sqrt{\frac{x+2}{5}} \) 

\[
\frac{x+2}{5} \geq 0 \\
x + 2 \geq 0 \\
x \geq -2 \\
\left[-2, \infty\right)
\]
Keep in mind that anytime you see a function containing a square root, the radicand of that square root must be non-negative (equal to zero or greater than zero).

Also, keep in mind that intervals must go in order from smallest to largest when going from left to right, just like a number line. On Example 1 part f., I simplified the inequality $\frac{x+2}{5} \geq 0$ to get $x \geq -2$. In order to convert this inequality to interval, I used a number line:

![Number line diagram]

This is how I came up with my answer in interval notation, $[-2, \infty)$. Since $-2$ is to the left of infinity on the number line, $-2$ must be to the left of infinity in my interval.

**Remember that just like a number line, an interval should always go from smallest to largest when going from left to right.**

Next we’ll look at functions defined by fractions, so we’ll need to be sure that the denominator of those fractions does not equal zero.
**Example 2:** Find the domain of each of the following functions, and list in interval notation. Use a number line to convert from inequalities to intervals, if necessary.

a. \( m(x) = \frac{x}{x-4} \)

b. \( n(x) = \frac{x+1}{x^2-9} \)

c. \( p(x) = \frac{\sqrt{x}}{x-1} \)

d. \( q(x) = \frac{1-\sqrt{2x}}{x^2+1} \)

\[ 2x \geq 0 \quad \text{AND} \quad x^2 + 1 \neq 0 \]
\[ x \geq 0 \quad \text{AND} \quad x^2 \neq -1 \]
\[ x \geq 0 \quad \text{AND} \quad x \neq \pm\sqrt{-1} \]

Since \( x \neq \pm\sqrt{-1} \) does not exist with real numbers, we can disregard that inequality and simply focus on \( x \geq 0 \).
e. \( r(x) = \frac{5+2\sqrt{8-2x}}{x^2+5x+6} \)

f. \( s(x) = \frac{\sqrt{3x-7}}{x^2+5x-6} \)

3x − 7 ≥ 0 AND \( x^2 + 5x - 6 \neq 0 \)

3x ≥ 7 AND \((x + 6)(x - 1) \neq 0 \)

\( x \geq \frac{7}{3} \) AND \( x + 6 \neq 0 \) AND \( x - 1 \neq 0 \)

\( x \geq \frac{7}{3} \) AND \( x \neq -6 \) AND \( x \neq 1 \)

\( \left[ \frac{7}{3}, \infty \right) \)

g. \( f(x) = \frac{1}{\sqrt{x+3}} \)

h. \( g(x) = \frac{x-4}{\sqrt{x-2}} \)
i. $h(x) = \frac{x}{\sqrt{x-1}}$

j. $j(x) = \frac{\sqrt{4-x}}{2-\sqrt{x}}$

**Answers to Examples:**

1a. $\left[-\frac{7}{2}, \infty\right)$; 1b. $\left(-\infty, \frac{8}{3}\right]$; 1c. $[-3, \infty)$; 1d. $\left(-\infty, \frac{1}{2}\right]$;

1e. $(-\infty, 4]$; 1f. $[-2, \infty)$; 2a. $(-\infty, 4) \cup (4, \infty)$;

2b. $(-\infty, -3) \cup (-3, 3) \cup (3, \infty)$; 2c. $[0, 1) \cup (1, \infty)$; 2d. $[0, \infty)$;

2e. $(-\infty, -3) \cup (-3, -2) \cup (-2, 4]$; 2f. $\left[\frac{7}{3}, \infty\right)$; 2g. $(-3, \infty)$;

2h. $(2, \infty)$; 2i. $[0, 1) \cup (1, \infty)$; 2j. $[0, 4)$;
